Table of acronyms

Acronym	Full Form
DNS	Domain Name System
HTTP	Hyper Text Transfer Protocol
IP	Internet Protocol
LAN	Local Area Network
MN	Mininet
NAT	Network Address Translation
PPCP	Pulse Position Coded Protocol
RAM	Random Access Memory
SDN	Software Defined Networking
TCP/IP	Transmission Control Protocol
VM	Virtual Machine
VPN	Virtual Private Network
WAN	Wide Area Network

Introduction

This post describes how I configured an Ubuntu virtual machine on VMware workstation for the installation of Mininet-a network emulation application. The purpose of this configuration is providing a lab to experiment and advance programmable networks that leverage software-defined networking (SDN). These are: installation of the necessary software; configuration of the Virtual machine and confirmation that Mininet is running as expected.

VM Ubuntu Installation

I will create an Ubuntu virtual machine with it; the steps as well as images of my processes are presented below.

- First, I downloaded the Ubuntu ISO file from Ubuntu website.
- In order to establish a new virtual machine, I then launched VMware
- It was called Advance Networking Ubuntu. This was a Linux operating system with the 64-bit version and the system having a 4 GB RAM, two cores and 30GB hard drive created dynamically using the network adapter – NAT.
- The ISO file of Ubuntu was incorporated as a bootable disk to the virtual machine.
- Finally, I started the virtual machine, and then installed the Ubuntu with update manager by going through the instructions on the screen.

Figure 1 – Successful Installation

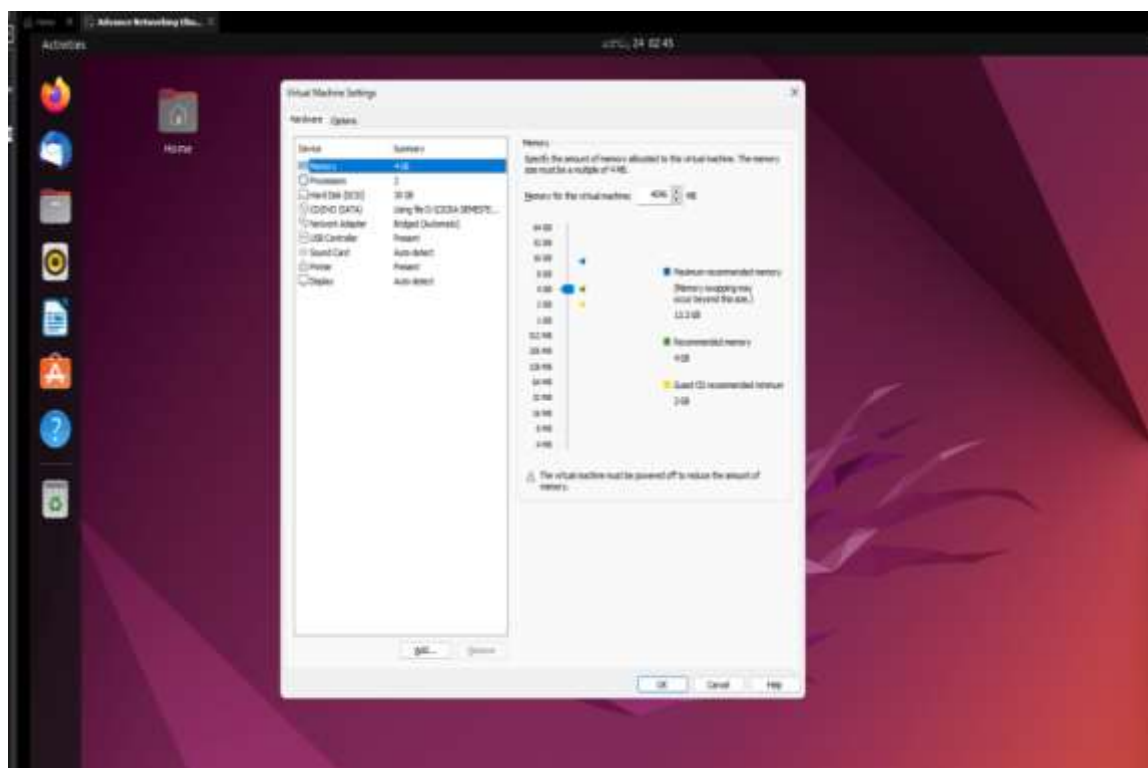

Figure 2 – Ubuntu VM Settings

Ping with Virtual machine

As it is now, the connectivity of the Ubuntu virtual machines and the host computer must be checked.

- I started the Ubuntu virtual machine first.
- In the Ubuntu terminal I checked the IP address of the system by typing the command `ifconfig`. Its number was 192.168.232.133. Here is a screen grab of it.

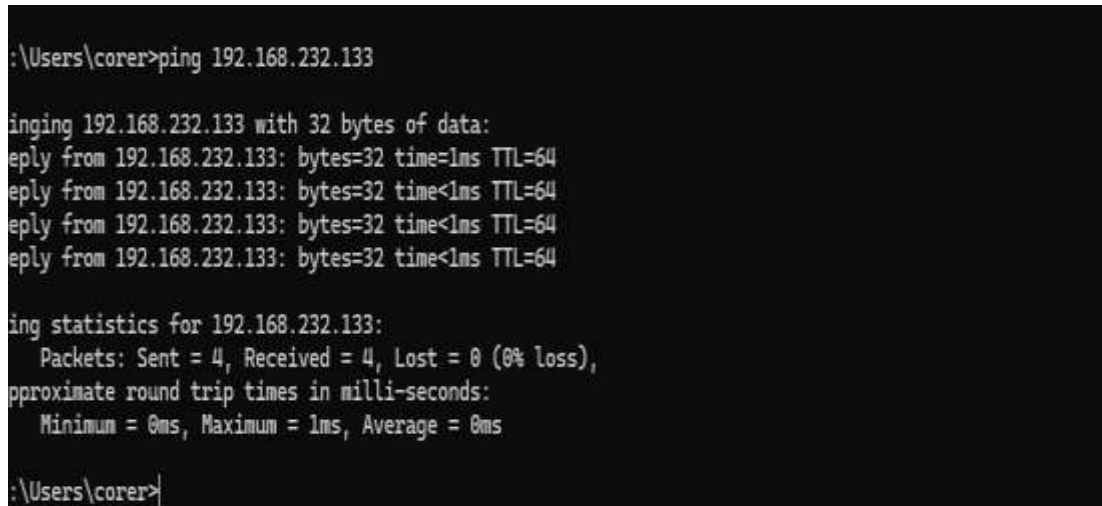

```
kenisha@kenisha-virtual-machine:~/Desktop/mininet$ ifconfig
ens33: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 192.168.232.133 netmask 255.255.255.0 broadcast 192.168.232.255
    inet6 fe80::bfb:32a1:7e07:a361 prefixlen 64 scopeid 0x20<link>
    ether 00:0c:29:a8:23:a3 txqueuelen 1000 (Ethernet)
    RX packets 50543 bytes 72769696 (72.7 MB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 8984 bytes 616082 (616.0 KB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
    inet 127.0.0.1 netmask 255.0.0.0
    inet6 ::1 prefixlen 128 scopeid 0x10<host>
    loop txqueuelen 1000 (Local Loopback)
    RX packets 9532 bytes 695352 (695.3 KB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 9532 bytes 695352 (695.3 KB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

kenisha@kenisha-virtual-machine:~/Desktop/mininet$
```

Figure 3 – Ubuntu VM ip address

- As a way of confirming if my host was connected to the Ubuntu virtual machine, I went back to my host computer and used the ping command on the Ubuntu machines IP address (ping 192.168.232.133). The host computer on which I conducted the experiment operated Windows 11. This is a screenshot of it.

A screenshot of a Windows command prompt window. The prompt shows the user typing 'ping 192.168.232.133'. The output displays four successful replies from the target IP address, each with 32 bytes of data, a time of less than 1ms, and a TTL of 64. Below the replies, it shows the ping statistics for 192.168.232.133: 4 packets sent, 4 received, 0 lost (0% loss), and approximate round trip times in milliseconds: Minimum = 0ms, Maximum = 1ms, Average = 0ms. The prompt ends with the user's cursor at the command line.

```
C:\Users\corer>ping 192.168.232.133

Pinging 192.168.232.133 with 32 bytes of data:
Reply from 192.168.232.133: bytes=32 time<1ms TTL=64
Reply from 192.168.232.133: bytes=32 time<1ms TTL=64
Reply from 192.168.232.133: bytes=32 time<1ms TTL=64
Reply from 192.168.232.133: bytes=32 time<1ms TTL=64

Ping statistics for 192.168.232.133:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 1ms, Average = 0ms

C:\Users\corer>
```

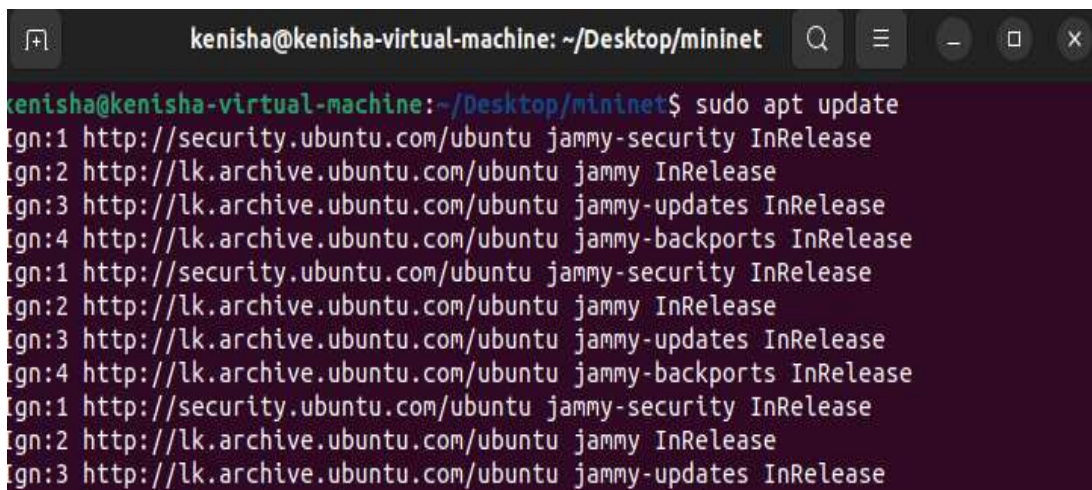

Figure 4 – Successful Pinging

- The good ping ensured that there was a positive interaction between the two machines.

Mininet Installation

I installed Mininet after confirming the interconnection of the host system with the newly created virtual machine.

- Initially, I launched the terminal in Ubuntu.
- Using the touch command, I first create a folder called mininet
- Used the command “sudo apt update” to update the package list.

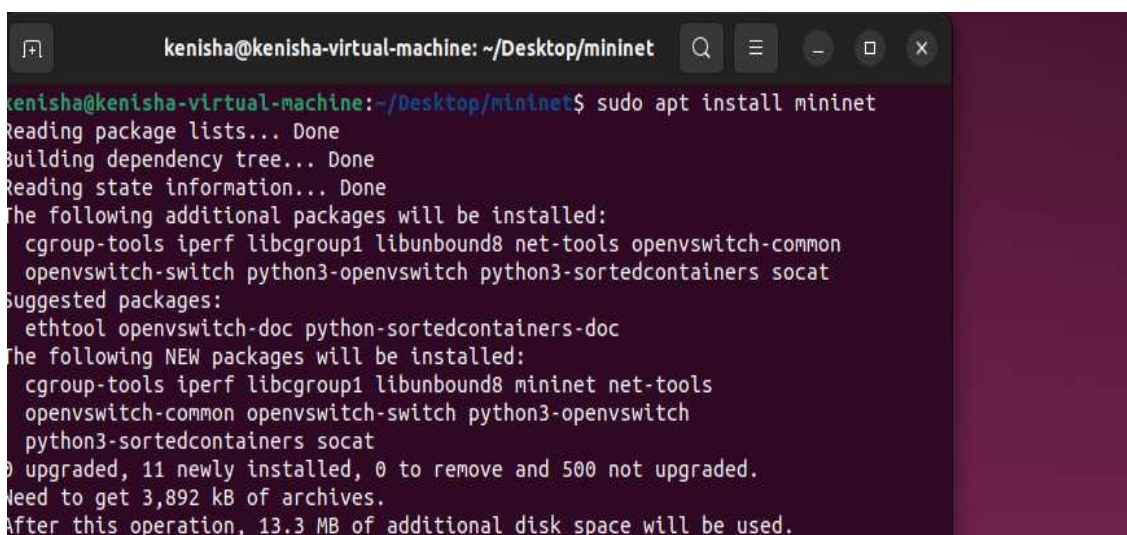

```

kenisha@kenisha-virtual-machine: ~/Desktop/mininet
kenisha@kenisha-virtual-machine:~/Desktop/mininet$ sudo apt update
Ign:1 http://security.ubuntu.com/ubuntu jammy-security InRelease
Ign:2 http://lk.archive.ubuntu.com/ubuntu jammy InRelease
Ign:3 http://lk.archive.ubuntu.com/ubuntu jammy-updates InRelease
Ign:4 http://lk.archive.ubuntu.com/ubuntu jammy-backports InRelease
Ign:1 http://security.ubuntu.com/ubuntu jammy-security InRelease
Ign:2 http://lk.archive.ubuntu.com/ubuntu jammy InRelease
Ign:3 http://lk.archive.ubuntu.com/ubuntu jammy-updates InRelease
Ign:4 http://lk.archive.ubuntu.com/ubuntu jammy-backports InRelease
Ign:1 http://security.ubuntu.com/ubuntu jammy-security InRelease
Ign:2 http://lk.archive.ubuntu.com/ubuntu jammy InRelease
Ign:3 http://lk.archive.ubuntu.com/ubuntu jammy-updates InRelease

```

Figure 5 – Ubuntu updated

- Next, as instructed in the assignment, I entered the command “sudo apt install mininet” to install mininet.

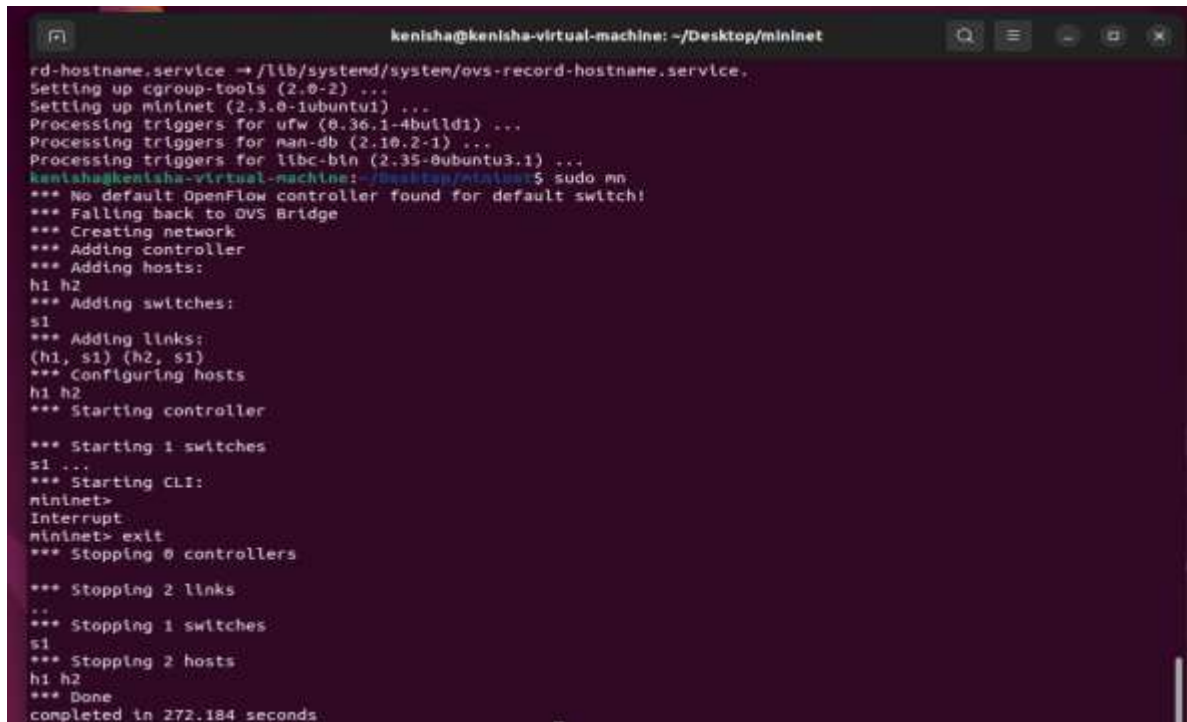

```

kenisha@kenisha-virtual-machine: ~/Desktop/mininet
kenisha@kenisha-virtual-machine:~/Desktop/mininet$ sudo apt install mininet
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
The following additional packages will be installed:
  cgroup-tools iperf libcgroup1 libunbound8 net-tools openvswitch-common
  openvswitch-switch python3-openvswitch python3-sortedcontainers socat
Suggested packages:
  ethtool openvswitch-doc python-sortedcontainers-doc
The following NEW packages will be installed:
  cgroup-tools iperf libcgroup1 libunbound8 mininet net-tools
  openvswitch-common openvswitch-switch python3-openvswitch
  python3-sortedcontainers socat
0 upgraded, 11 newly installed, 0 to remove and 500 not upgraded.
Need to get 3,892 kB of archives.
After this operation, 13.3 MB of additional disk space will be used.

```

Figure 6 – Installing mininet

- In order to begin using Mininet I keyed in the command “sudo mn” to start the Mininet emulator with minimum topology which consists of a switch connected to two hosts.

```

kenisha@kenisha-virtual-machine: ~/Desktop/mininet
rd-hostname.service → /lib/systemd/system/ovs-record-hostname.service.

Figure 7 – Creating Network Topology

Answer the following questions.

Question A

- a. **In your opinion what is the difference between computer networks and network security? Elaborate your answer in no more than 250 words.**
- Network security and computer networks are two related fields that are critically important to modern information technology infrastructures. Connectivity comes from computer networks but since there is always risk and vulnerabilities in existence, network security is there to safeguard this connectivity. (Myers, 2011)
 - Computer networks are systems of interconnected computers, communicating devices, TCP/IP infrastructure, and other peripherals such as servers, switches, routers etc. Depending on their size and coverage they are generally regarded as the Internet, WANs or LANs. PPP, DNS and HTTP are categorized in protocols in which networks employ to regulate other devices' data transfer. They tend to focus on side functionality such as being effective, measurable and reliable in supporting programs such as files, emailing and web browsing. The idea of a computer network is that regardless of whether users are in the same building in the same office or in different parts of the world, interconnectivity should be seamless.
 - On the other hand, network security is involved with protecting these networks' systems and data against intrusions, breaches and attacks. With reference to protection provided to the network's infrastructure, it involves installation of technologies such as intrusion detection/prevention systems, firewalls and antivirus. VPN, encryptions, secure authentications etc. all ensure that the individual's private information remains 'private'. In addition to dwellers, Regulations and Protocols also form part of the network security since they help regulate behaviors and expose weaknesses.

Question B

b. What is the difference between Emulator Testing and Real Device Testing?

Elaborate your answer in no more than 250 words.

- Let me clarify that emulator testing, and real device testing are two testing approaches out there in mobile application testing each of which has its function and serves a particular purpose in testing. (STALLINGS, 2008)
- Emulator testing is the use of software to emulate actual devices in an effort to measure their behavior. Sometimes emulators are used right at the start of the application development process because they are cheap and easy to run. They can run the application on emulators without having the actual devices and can test the application on various operating system versions, resolutions of display possible configurations not possible with normal physical devices. The primary use of emulators is in checking the functionality and unadulterated use – barebone user interactions because of special features such as log tracking, error detection, and breakpoints. In particular, they work faster while doing repetitive functions such as running scripts. But as for the emulation, it is constrained in a way that it cannot fully mimic real conditions, including power management, network conditions, and the hardware specifics of the device in question (cameras, sensors, and fingerprint readers). That is why they are less effective for the assessment of user experience as well as for performance testing. (Tanenbaum, 2013)
- On the other hand, real device testing involves the use real gadgets to test the applications under test. As a result of the real condition, it means hardware behavior, system compatibility, network fluctuations, touch sensitivity, gestures, etc., this method only provides the best result. However, in an effort to establish the functionality of the app as well as the reliability and response time where and when the end user would apply the application, actual device testing is required. But, in contrast to emulation testing, it consumes both time and a significant amount of money to have diverse devices under the test.

(305 Words)

Conclusion

- In conclusion, this study provided a step by step guide to creating Mininet through VMware on an Ubuntu based virtual machine. These include installation of necessary software, checking the Mininet settings as directed and checking on the connectivity in the network. Each of the steps in the program was shown with pictures, which meant that everyone who was following the sites described in the text, not only read but understood the content and were able to get the information they needed. This instructions enable users to assess and instantiate Mininet conveniently in their emulation environment.
- The questions posed in the enquiries delineated new characteristics in program building and computer science. This provided us with first glimpse of difference between the computer networks and network security and where network security stands on the spectrum: networks act as a connection while security protects from connections. In a digital environment, however, both components are of equal significance due to this special double focus: On the one hand, it is possible for devices to exchange information with each other behind the user's back.
- Lastly, in software validation we also looked at the conflicting ideas of emulator testing and real device testing. Even though the emulator testing contributes to the questions of affordability and flexibility it fails to take into account the reality of life. Still, due to the assessment on actual devices which has certainly distinct layouts, Real Device Testing gives a fairer result since it pinpoints the issues which are distinctive to such device and ensures that elements of the app are stable and functional across different scenarios. There can be no doubt as to the fact that these tests are indispensable since they create the possibilities for the establishment of stable and accessible software tools that can be utilized against the connected enemy of today.
